

Adverse scenario for the European Insurance and Occupational Pensions Authority's EU-wide pension fund stress test and for the European Securities and Markets Authority's money market fund stress-testing guidelines in 2019

Introduction

The European Supervisory Authorities, in cooperation with the European Systemic Risk Board (ESRB), are requested by legislation to use stress tests in order to assess the resilience of financial institutions or market participants to adverse market developments. As part of this cooperation, the ESRB designs scenarios of adverse economic and financial market developments.

The ESRB was asked to provide adverse financial market scenarios for the stress-testing exercises planned by the European Insurance and Occupational Pensions Authority (EIOPA) and the European Securities and Markets Authority (ESMA). Specifically, EIOPA will be undertaking its third stress test for institutions for occupational retirement provision (IORP), while ESMA is developing guidelines for managers of money market funds (MMF) who are required to conduct internal stress tests and report the results to national competent authorities and ESMA.¹

The European Central Bank, in collaboration with the ESRB, EIOPA and ESMA, has developed the narrative and has calibrated the adverse scenario for both exercises described in this document,² which has been approved by the ESRB General Board and transmitted to EIOPA and ESMA.

Designing a single scenario increases the coherence between the stress-testing exercises, allowing for an appropriate response from the institutions and companies included in the scope of the exercises. The risk factors to be considered in this scenario differ between the stress-testing exercises:

- ESMA's stress-testing guidelines focus on short maturities (between one month and two years), while the EIOPA stress test focuses on long maturities (e.g., five years);
- despite the importance of interest rates for both exercises, the MMF exercise also considers asset liquidity and the IORP exercise also considers equity prices, residential real estate prices and inflation swap rates;

¹ Article 28 of the MMF Regulation provides that ESMA shall develop guidelines that establish common reference parameters of the stress test scenarios to be included in the stress tests that managers of MMFs are required to conduct.

² The scenario presented in this document is not a forecast. It should not be interpreted as either the ESRB's expectations about future economic and financial developments or any unintended consequences of future monetary policy decisions. It constitutes a severe yet plausible scenario that could arise if a risk environment such as the one explained in the note were to materialise.

The list of risk factors to be considered in each exercise can be found in Annex B.

This document presents the main sources of risk that lead to the adverse scenario and the key features that EIOPA and ESMA consider relevant to the IORP and MMF sectors. The calibration of the scenario has benefited from guidance from EIOPA and ESMA, and from discussions with ESRB member institutions. The methodology underlying the calibration of the financial shocks is based on the same models used in previous stress tests.³ The shocks reported should be interpreted as one-off, instantaneous and permanent shifts in asset prices relative to their end-2018 levels.⁴

Assumptions about long-term risk premia, which are needed for other components of EIOPA's stress test, are developed by EIOPA and are not presented in this document. Likewise, assumptions on redemptions which are needed for ESMA's MMF stress test are developed by ESMA and presented in the separate methodological document. In addition, guidance on applying the scenario is provided by EIOPA and ESMA and is not covered here.

Systemic risks and vulnerabilities addressed by the scenario

The scenario reflects the ESRB's assessment of prevailing sources of systemic risk for the EU financial system:

- 1. repricing of risk premia in global financial markets;
- 2. persistent weaknesses in balance sheets of EU banks, insurers and pension schemes;
- 3. debt sustainability challenges in EU sovereign, corporate and household sectors;
- 4. vulnerabilities in the EU shadow banking sector and contagion to the financial system.

Narrative and calibration of the scenario

The methodology for the scenario calibration is based on a non-parametric application of a multivariate copula model.⁵ The scenario is the outcome of several simulations based on different triggers that reflect the main sources of financial stability risks, with a special focus on the repricing of some types of assets: swap rates (in the EU, the United States and emerging market economies), government credit spreads and equity prices in the EU and other advanced economies, and bid-ask spreads on government bonds. The calibration sample and probability of the triggering events have been chosen to reflect the main features of the scenario in the calibration and were motivated by the narrative developed jointly with

³ See, for example: https://eiopa.europa.eu/Pages/Financial-stability-and-crisis-prevention/Occupational-Pensions-Stress-Test-2017-aspx.

⁴ For this reason, the severity of the scenario designed for EIOPA and ESMA cannot be directly compared with that of the European Banking Authority (EBA), because in the EBA scenario, the overall impact depends on the accumulation of shocks occurring over three years. In addition, the narrative of the scenario differs from that of the EBA as it is more focused on risk factors linked to the IORP and MMF sectors, even though they are based on the same overall risk assessment process.

⁵ See the methodological note describing the Financial Shock Simulator.

EIOPA and ESMA. More precisely, the sample chosen for the calibration spans from January 2004⁶ to December 2018 and the probability of the shocks to the triggering variables is below 1% over the horizon of one quarter.

The scenario is assumed to be initiated by an abrupt reversal in global risk premia, which is deemed the most relevant financial stability risk. While the shocks to interest rates are higher on short maturities owing to greater uncertainty and risks to growth caused by political tensions, concerns in the euro area (EA) about growth in the long term (for demographic reasons, for example) would result in lower shocks for long-term maturities. The swap rate curve would shift upwards by 80 basis points in the EA for the one-year maturity and by more than 140 basis points in other major advanced economies (see Charts 1 and 2). The swap rate curve would shift upwards by 25 basis points in the EA for the ten-year maturity and by more than 40 basis points in other major advanced economies (see Charts 1 and 2).

Chart 1: Shock to swap rates (basis points)

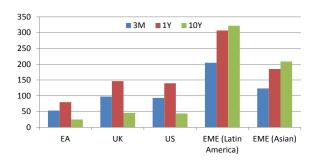

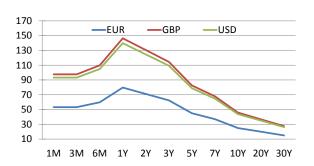

Chart 2: Distribution of swap rate shocks across different maturities (basis points)

The overall repricing of risk premia would raise concerns about the debt sustainability of some EU Member States, leading to a widening of yield spreads between those government bonds and the equivalent German bonds. On average, ten-year government bond yields in the EU would increase by about 110 basis points, with a range between 29 basis points and 347 basis points under the adverse scenario (see Chart 3). The variance across EU countries is lower on one-year government bond yields, where shocks range from 60 basis points to 213 basis points. Overall, one-year government bond yields in the EU would increase by 130 basis points on average (see Chart 4). Other advanced economies experience a shock of over 155 basis points for one-year government bond yields and of around 143 basis points for ten-year government bond yields (see Chart 5). Government bond yields respond both to the increase in risk-free rates and to the widening of the spreads owing to concerns about debt sustainability. For this reason the distribution of the shocks to government bond yields is bimodal.

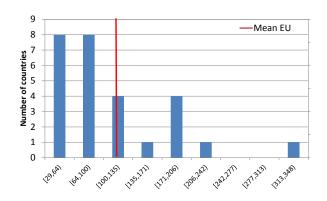

|3

⁶ The model uses daily data and the majority of time series have sufficient data as of 2004.

Chart 3: Distribution of shocks to ten-year government bond yields in EU (basis points)

Chart 4: Distribution of shocks to one-year government bond yields in EU (basis points)

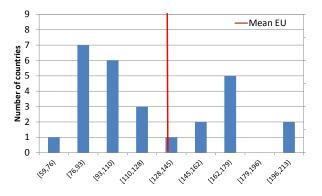

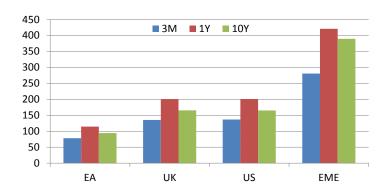

Chart 5: Shocks to government bond yields across countries (basis points)

In addition, yields on non-financial corporate and bank debt would increase, following the generalised increase in risk premia (see Chart 6). In the banking sector, shocks to credit spreads would be aggravated by fundamental concerns about prospective mark-to-market losses on fixed-income assets, bringing about an increase of more than 340 basis points for lower-rated financial corporations. AAA-rated non-financial corporate bond yields would also increase by about 120 basis points in the EU, but the impact on credit spreads would be more pronounced for lower-rated issuers, reaching 180 basis points for CCC-rated non-financial corporate bonds.

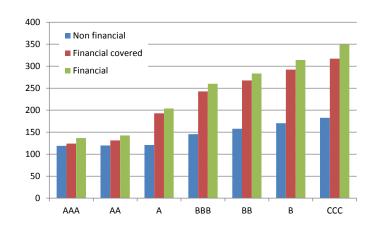

Chart 6: Shocks to corporate bond yields in EU (basis points)

The repricing of risk premia would also bring about a substantial drop in equity prices, amplified by a general sell-off of equities by the non-banking sector. Overall, equity prices in the EU would decline by about 39% (see Chart 7). Residential and commercial real estate prices would also decline significantly, by 20% and 31%, respectively, with respect to the baseline at EU level (see Chart 8).

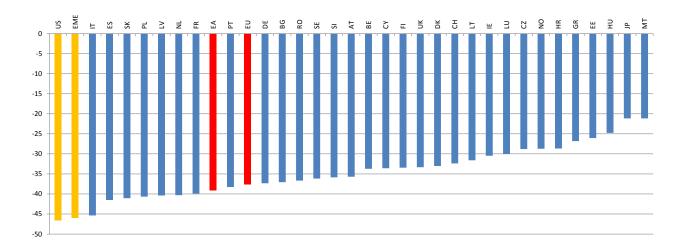

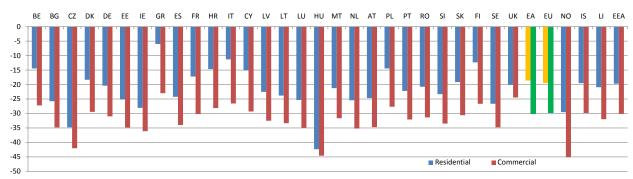

Chart 8: Shocks to residential real estate prices and commercial real estate prices (%)

The value of investments in private equity and hedge funds would fall by between 32% and 50% (see Chart 9). Commodity prices would also decline significantly, between 28% and 47%.
